Installation Guide

Mobile

The 'apk' file is given with the final package, it should be deployed to the mobile devices that have the Android version of at least 4.0 (Ice Cream Sandwich).

The source code is written with Titanium SDK, one can be create a new project with the existing source code and then continue to develop. It is also possible that the application can be compiled and built for other platforms such as Windows Phone.

Website

All of the compiled packages are given with the final package. To deploy the server side of the website, at least Apache Tomcat version 7 should be used. One can follow the instructions given in the [website](#) of the Apache Tomcat, in order to install the given webpage to a local Tomcat Servlet.

The Source code is written in Java programming language, therefore any SDK suitable with java can be used to develop the server side and the Website of our project.

Database

Fortunately, only the server side code connects to our database and run queries. At the moment, our database is up and working in the Amazon Server as a MySQL db instance. If it crashes for some reason, one can easily create a new database to run the application. An SQL file is given with the final package that includes all the necessary queries to create the database.
